Heat conduction across a non-zero temperature difference.

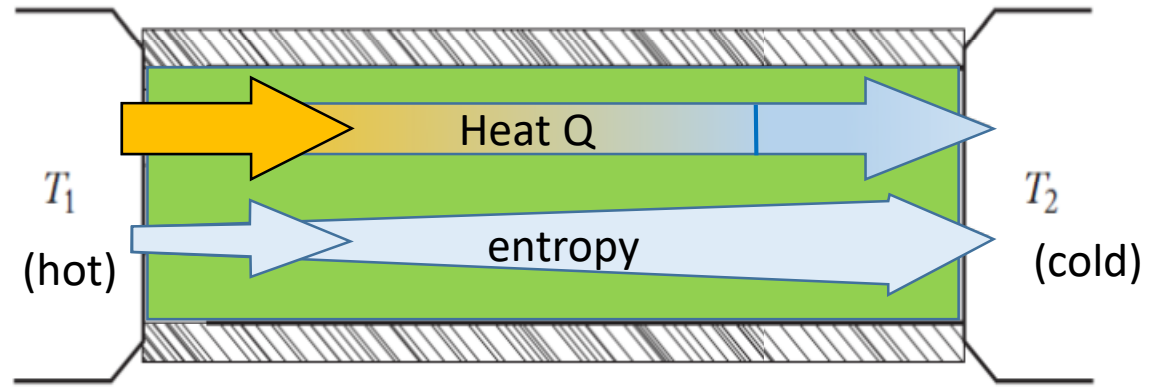

Consider the green rod:

entropy in = Q/T_1 , entropy out = Q/T_2 .

$$\frac{Q}{T_2} > \frac{Q}{T_1}$$

(Entropy out of rod) > (entropy into rod)

So the rod is generating entropy; hence **irreversible**

Heat engine:

$$\frac{Q_2}{T_2} = \frac{Q_1}{T_1}$$

Entropy out = entropy in

hence **reversible**

But what is it?

- (1) Entropy is *the absence of structure*.
- (2) Entropy is *freedom to explore*.
- (3) Entropy increase is the *dispersal of energy*.
- (4) Entropy is that which separates the future from the past.

To understand (1), consider also (2).

The 'freedom' here is the fact that many internal microscopic rearrangements correspond to the same macroscopic parameters (e.g. energy, volume) and only the latter are constrained by the environment.

Entropy change in free expansion

The Hammers

*Noise of hammers once I heard,
Many hammers, busy hammers,
Beating, shaping, night and day,
Shaping, beating dust and clay
To a palace; saw it reared;
Saw the hammers laid away.*

*And I listened, and I heard
Hammers beating, night and day,
In the palace newly reared,
Beating it to dust and clay:
Other hammers, muffled hammers,
Silent hammers of decay.*

Ralph Hodgson

Thermodynamics lecture 5.

W.A.L.T.

1. Entropy cannot decrease in an isolated system
2. How to calculate entropy changes
3. Gaining familiarity and intuition about entropy
4. Gibbs paradox and “entropy of mixing”
5. Maxwell daemon and other thought-experiments
6. Some practical heat engines

Gibbs paradox

(a) identical gases

$$\Delta S_{\text{id}} = 0$$

identical gases

(b) different gases

$$\Delta S_{\text{dif}} = 2Nk_B \ln 2$$

different gases

N = number of molecules in each part.

Here $N = 3$

The issue is, why is the mixing in (a) not an increase in entropy?

Answer requires quantum theory! The notion of **genuine or absolute indistinguishability**:

- *All states of a system which differ only by a permutation of identical particles must be considered one and the same state.* So the “mixing” in (a) does not change the state.

Reversible mixing (i.e. without free expansion)

Semi-permeable membrane

Retains gas A, lets gas B through

Retains gas B, lets gas A through

Note: the forces owing to pressure on the piston are balanced.
Quasistatic, no hysteresis \rightarrow reversible \rightarrow no entropy change

Maxwell's daemon

(daemon = one who enacts or mediates an interaction/process)

Maxwell's idea:

- Use observation to decide when to open the trap door.
- Thus separate the molecules (e.g. bring them all to one side, or separate slow from fast).
- Hence cause the entropy of the system to go down, with no net energy flow in or out.

Maxwell's daemon

(daemon = one who enacts or mediates an interaction/process)

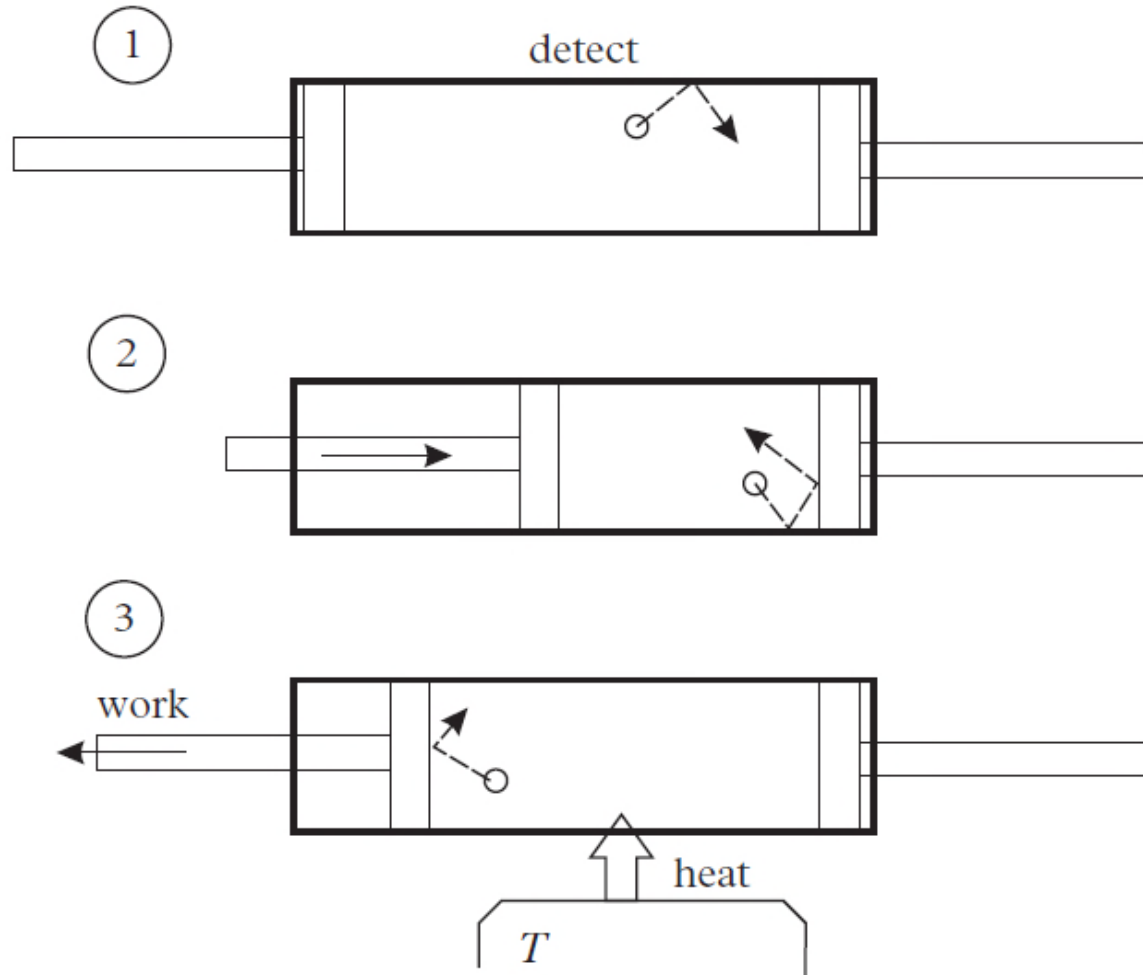

Maxwell's idea:

- Use observation to decide when to open the trap door.
- Thus separate the molecules (e.g. bring them all to one side, or separate slow from fast).
- Hence cause the entropy of the system to go down, with no net energy flow in or out.

Resolution:

The daemon is itself a physical system, and must either store the information (in which case it is not acting in a cycle) or else release it to the environment (in which case the entropy of the environment goes up).

Szilard engine

Detect where the molecule is.

Compression:
molecule is on the
other side so no work
needs to be supplied.

Isothermal expansion:
obtain work W while
heat Q flows in.

The memory of the detector then has to be cleared

Feynman-Smoluchowski ratchet

Exploit thermal fluctuations to raise the load.
Seems to allow violation of Kelvin statement?

Feynman-Smoluchowski ratchet

Exploit thermal fluctuations to raise the load.

When the forward and reverse processes are balanced, we find

$$Q_1/Q_2 = T_1/T_2$$

--- it's a heat engine obeying the Second Law.

The Principle of Detailed Balance (in conditions of thermodynamic equilibrium)

Each internal process goes at the same rate as the direct reverse process between the same two states.

Internal combustion engine

Otto cycle

$$Q_1 = \int_{T_2}^{T_3} C_v dT = C_v(T_3 - T_2),$$

$$Q_2 = - \int_{T_4}^{T_1} C_v dT = C_v(T_4 - T_1)$$

$$\eta = \frac{W}{Q_1} = \frac{Q_1 - Q_2}{Q_1} = 1 - \frac{T_4 - T_1}{T_3 - T_2} = 1 - r^{1-\gamma}$$

$r \equiv V_1/V_2$ is the *compression ratio*

Stirling engine

No valves, no explosions

→ smooth and low-maintenance

Expand while hot; compress while cold
