

The Light Cone

The Light Cone

Active Future

Events later than A and separated from A by a timelike interval

Future light cone

Events later than A and separated from A by a zero (lightlike) interval

"Neutral" or "unreachable" region

Events separated from A by a spacelike interval
Every such event can be made to look either earlier than A or later than A by suitable choice of inertial reference frame

Past light cone

Events earlier than A and separated from A by a zero (lightlike) interval

Passive past

Events earlier than A and separated from A by a timelike interval

One way partially to reassemble exploded view

Events that an observer at A can influence by what he does now or in the future

Events that an observer who has arrived at A can no longer alter

Another way partially to reassemble exploded view

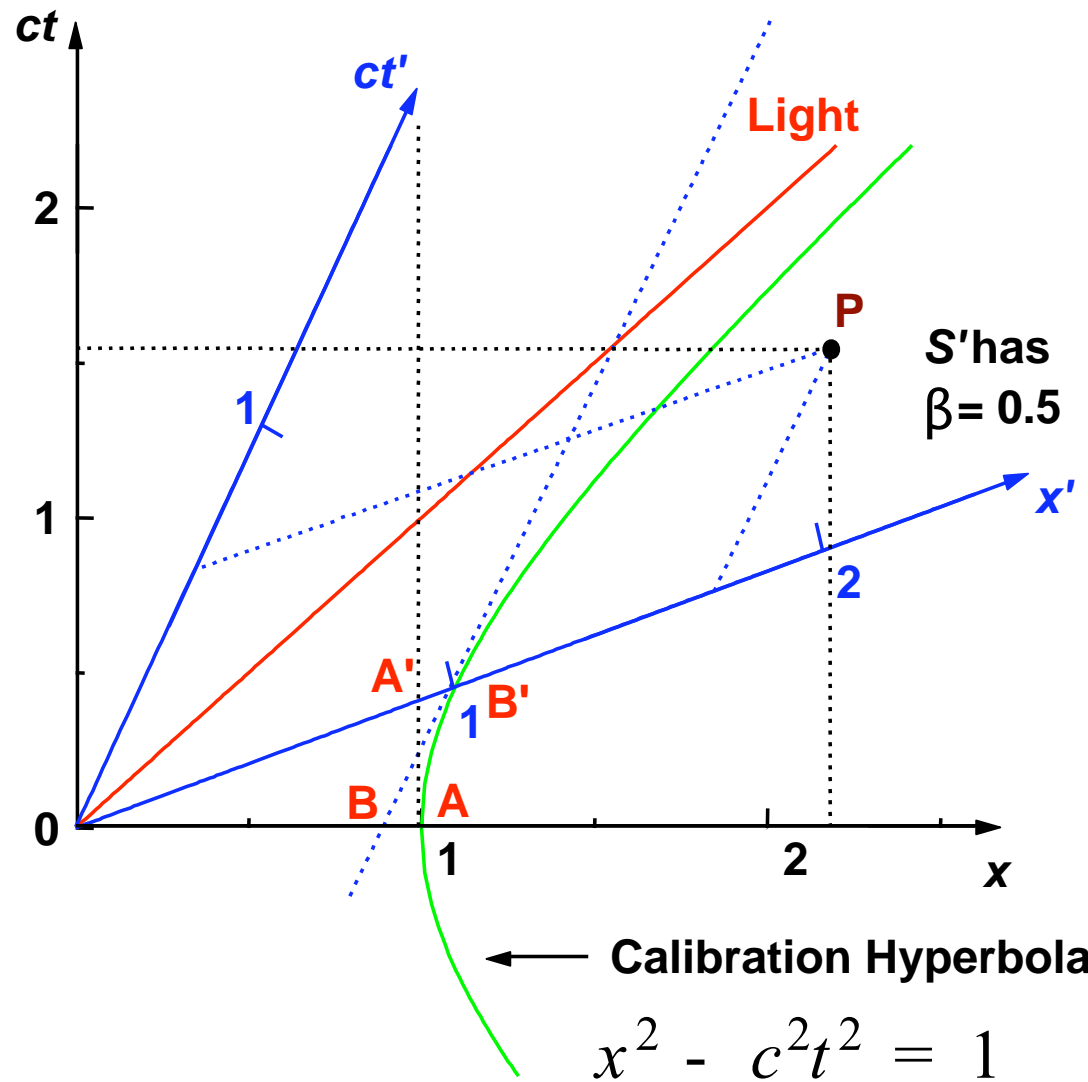

Events that an observer at A may yet experience if nothing is shrouded from his gaze

Events in which observer at A has participated—either actively or as an observer—or from which he may have received knowledge or effects

Minkowski Diagram

Unit distance in S is OA
 Unit distance in S' is OB'
 Stick length OA' in S' < 1 (OB')
 Stick length OB in S < 1 (OA)
 Thus we have **SYMMETRY** in the Lorentz contraction

← Calibration Hyperbola

$$x^2 - c^2t^2 = 1$$

Minkowski Diagram explaining light cone

Event P can be influenced by event O, time ordering is preserved. P **always** occurs after O in all frames.

Event Q is outside the light cone and time ordering is not preserved. In S' , Q occurs **before** O, whilst in S , Q occurs **after** O.

Relative to What?

$$x' = 8 \text{ m}$$

$$ct' = 10 \text{ m}$$

$$x = 0 \text{ m}$$

$$ct = 6 \text{ m}$$

$$x'' = 20 \text{ m}$$

$$ct'' = 20.88 \text{ m}$$

A flash path as recorded in three different inertial frames, showing emission and reception events after reflection at a mirror. The Super-Rocket moves to the right relative to the rocket.

Δ is INVARIANT

Spacetime Diagrams of the Same Event in Three Different Inertial Frames

LABORATORY
SPACETIME MAP

ROCKET
SPACETIME MAP

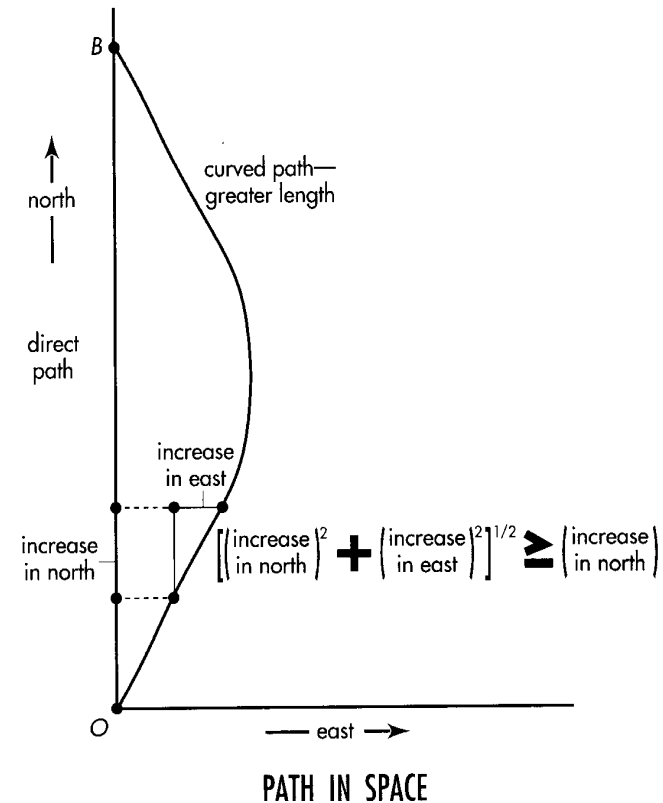

SUPER-ROCKET
SPACETIME MAP

The calibration hyperbola in each diagram satisfies the equation for the invariant interval (or proper time), which has the same value in all three inertial frames:

$$(\text{interval})^2 = (\text{space})^2 - (\text{time})^2$$

Principle of Maximal Ageing

Path in space: In Euclidean geometry the curved path has greater length

Worldline in spacetime: In Lorentz geometry the curved worldline is traversed in the shorter proper time

Causality – Faster Than Light?

Klingon
("laboratory")
spacetime diagram

The Klingon worldline is the vertical time axis. The Treaty of Shalimar is followed four years later by the Great Betrayal (0) at which Klingons launch the Super, which moves at three times light speed. Travelling from left to right, the Super passes one Federation colony (1) and then another (2). Finally the Super destroys the retreating ship of Federation negotiators (3).

"Rocket" spacetime
diagram of departing
Federation negotiators

In this frame their destruction comes first (3), followed by the passage of the Super from right to left past Federation colonies in reverse order (2 followed by 1). Finally the Super enters the Klingon launcher without doing any further damage (0). Cause and Effect are violated!

Consider a moving train with a light bulb in the middle. If you turn the light bulb on, light will travel both toward the front of the train and also toward the back of the train with speed $c = 3 \times 10^8 \text{ ms}^{-1}$.

From the point of view of the observer riding on the train, the distances from the light bulb to the front and back ends of the train are the same so *the light will reach both ends at the same time*.

However, from the point of view of the person on the ground, the front of the train is moving away from the light coming toward it while the back of the train is moving closer to the light coming toward it. This means that the distance covered by light going forward will be longer than the light going backwards. And since the *speed of light* is c in both directions for the observer on the ground also, *the light will reach the back of the train before it reaches the front of the train*.

In the frame fixed to the moving train,
the beams of light will reach both ends
of the train **at the same time**.

In the frame fixed to the ground,
the light reaches the back of the train
before it reaches the front.

In the frame moving faster than the train
the light reaches the back of the train
after it reaches the front.

The concept of *before* and *after* actually depends on the observer. Look at the spacetime diagram opposite. Light from the light bulb reaches the back end of the train at **A**, while it reaches the front end of the train at **B**. All observers are observing the same two events **A** and **B**. The spacetime points at which they occur are frame independent.

However, the *chronological order* of the events are frame dependent:

- In the frame fixed to the ground (x, t), **A** happens *before* **B**.
- In the frame fixed to the train (x', t'), **A** and **B** happen *at the same time*.
- In the frame fixed to the sports car (x'', t''), **A** happens *after* **B**.

This is the unavoidable consequence of the experimental fact that the *speed of light* is the same for all *inertial observers*.

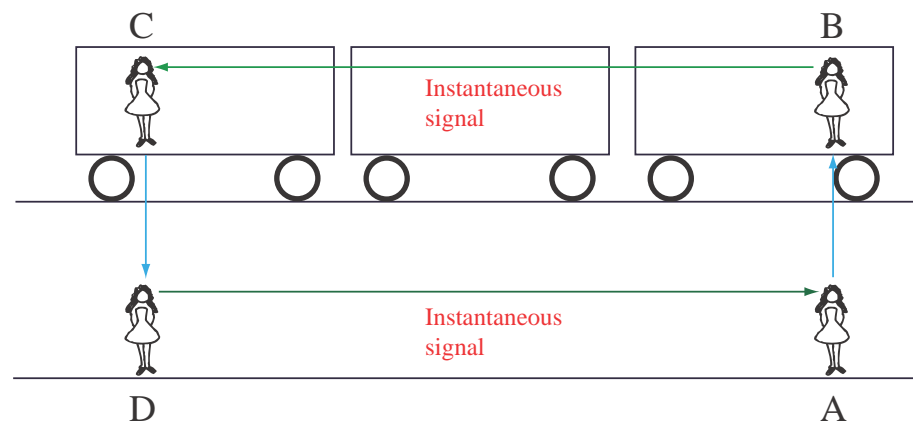

Let's consider another example. This thought experiment is discussed in Chapter 7 of the book "The Einstein Paradox and other Science Mysteries Solved by Sherlock Holmes" by Colin Bruce (Perseus Books, ISBN 0738200239).

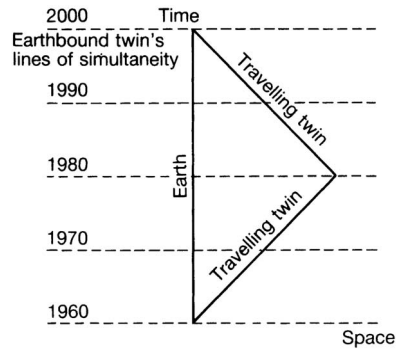

Assume that *instantaneous communication* were possible between remote points. In the spacetime diagram below, A and D are standing by the railroad tracks along which a speeding train passes by carrying B and C. Consider the following sequence of events:

1. A sends a message to B as the leading car carrying B passes by.
2. B relays the message to C riding the last car of the train via the *instantaneous communication* device.
3. C relays the message to D who is standing by the railroad tracks.
4. D relays the message back to A via the *instantaneous communication* device.

It is clear from the spacetime diagram that A will receive the message from D *before* she has sent out the original!

The Twins Paradox

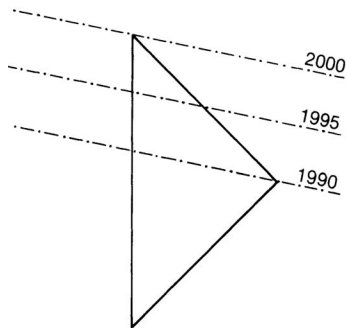

Earth-bound twin's lines of simultaneity

Travelling twin's lines of simultaneity on outward journey

Here $\gamma = 2$

Travelling twin's lines of simultaneity on return journey

Travelling twin's lines of simultaneity on both outward and return journey

The Twins Again

Alternative worldlines (direct OPB and indirect OQB) between events O and B. Note that in the rocket rest frame we need two invariant hyperbolae to show how events Q and B transform. The direct worldline OPB has longer proper time – greater ageing – as computed using measurements from either frame.

Direct world lines show **maximal proper time**

The Speeding Rocket

Initial mass = m_i

Final mass = m_f

Exhaust speed = w

Final speed = u

We have:

$$\frac{m_i}{m_f} = \left[\frac{c+u}{c-u} \right]^{c/2w}$$

For $w = 10 \text{ kms}^{-1}$ we get, for $u = \frac{1}{2} c$:

$$\frac{m_i}{m_f} = 10^{7157}$$

But for $w \sim c$ we get: $\frac{m_i}{m_f} \approx \sqrt{3}$

Is Space Travel Possible?

Suppose you took a trip across the Universe in a spaceship, accelerating all the time at one Earth gravity g . How far would you travel in how much time?

See <http://casa.colorado.edu/~ajsh>

Time elapsed on spaceship in years	Time elapsed on Earth in years	Distance travelled in light years	To
0	0	0	Earth (starting point)
1	1.175	.5431	
2	3.627	2.762	
2.337	5.127	4.223	Proxima Centauri
3.962	26.3	25.3	Vega
6.60	368	367	Pleiades
10.9	2.7×10^4	2.7×10^4	Centre of Milky Way
15.4	2.44×10^6	2.44×10^6	Andromeda galaxy
18.4	4.9×10^7	4.9×10^7	Virgo cluster
19.2	1.1×10^8	1.1×10^8	Coma cluster
25.3	5×10^{10}	5×10^{10}	Edge of observable Universe
